Image Processing
OpenCV

Intel® OPEN SOURCE COMPUTER VISION LIBRARY

Based in part on slides by Victor Eruhimov, Itseez
Goals

Develop a universal toolbox for research and development in the field of Computer Vision
We will talk about:

Algorithmic content
Technical content
Examples of usage
Trainings
OpenCV algorithms
OpenCV Functionality
(more than 350 algorithms)

Basic structures and operations
Image Analysis
Structural Analysis
Object Recognition
Motion Analysis and Object Tracking
3D Reconstruction
Basic Structures and Operations

File IO and capturing
Multidimensional array operations
Dynamic structures operations
Drawing primitives
Utility functions
Basic Structures and Operations

Multidimensional array operations include operations on images, matrices and histograms. In the future, when I talk about image operations, keep in mind that all operations are applicable to matrices and histograms as well. Dynamic structures operations concern all vector data storages. They will be discussed in detail in the Technical Section. Drawing primitives allows not only to draw primitives but to use the algorithms for pixel access. Utility functions, in particular, contain fast implementations of useful math functions.
File IO and Capturing

Simple OpenCV example:

```c
#include <stdio.h>
#include <opencv2/opencv.hpp>
using namespace cv;

int main(int argc, char** argv ) {
    if ( argc != 2 ) { printf("usage: DisplayImage.out <<Image_Path>>\n"); return -1; }

    Mat image;
    image = imread( argv[1], 1 );
    if ( !image.data ) { printf("No image data \n"); return -1; }

    namedWindow("Display Image", WINDOW_AUTOSIZE);
    imshow("Display Image", image);
    waitKey(0);
}
```
File IO and Capturing

CMake supports OpenCV as well so you can use a configuration file similar to using VTK:

```cmake
# Minimum required version of CMake
cmake_minimum_required(VERSION 2.8)

# Create the project
project( DisplayImage )

# Find the OpenCV package
find_package( OpenCV REQUIRED )

# Include directories
include_directories( 
  ${OpenCV_INCLUDE_DIRS} )

# Add the executable
add_executable( DisplayImage 
  DisplayImage.cpp )

# Link the executable with OpenCV libraries
target_link_libraries( DisplayImage 
  ${OpenCV_LIBS} )
```
File IO and Capturing

OpenCV supports a long list of file formats already that it is capable of loading directly. These include (via imdecode):

- Windows bitmaps - *.bmp, *.dib (always supported)
- JPEG files - *.jpeg, *.jpg, *.jpe (see the Notes section)
- JPEG 2000 files - *.jp2 (see the Notes section)
- Portable Network Graphics - *.png (see the Notes section)
- Portable image format - *.pbm, *.pgm, *.ppm (always supported)
- Sun rasters - *.sr, *.ras (always supported)
- TIFF files - *.tiff, *.tif (see the Notes section)
File IO and Capturing

As you saw from the example, images are typically represented as matrices, i.e. a 2x2 configuration of pixels, in OpenCV.

As data structure, OpenCV provides cv::Mat to store those images
File IO and Capturing

OpenCV also supports various video codecs. There is native support for:

<table>
<thead>
<tr>
<th>Codec</th>
<th>Format</th>
<th>Color</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AVI</td>
<td>'DIB'</td>
<td>RGB(A)</td>
<td>Uncompressed RGB, 24 or 32 bit</td>
</tr>
<tr>
<td>AVI</td>
<td>'I420'</td>
<td>RAW I420</td>
<td>Uncompressed YUV, 4:2:0 chroma subsampled</td>
</tr>
<tr>
<td>AVI</td>
<td>'IYUV'</td>
<td>RAW I420</td>
<td>identical to I420</td>
</tr>
</tbody>
</table>

Also, OpenCV can be compiled with support for ffmpeg, which supports various different formats, including: H.264, MJPG, MPEG, Quicktime, …
File IO and Capturing

OpenCV can also be used to capture images from recording devices, such as cameras, directly.

Both reading and capturing images are encapsulated in the VideoCapture class of OpenCV.

To open a file or get data from a capture devices use

```cpp
bool VideoCapture::open(const string& filename)
bool VideoCapture::open(int device)
```

You can release the device/close the file via

```cpp
void VideoCapture::release()
```
File IO and Capturing

When recording from a capture device, you can grab and then retrieve the image:

```cpp
bool VideoCapture::grab()
bool VideoCapture::retrieve(Mat& image,
                           int channel=0)
```

For reading the next image from an already opened file simply use the `read` method:

```cpp
bool VideoCapture::read(Mat& image)
```

Alternatively, you can use the usual C++ stream operators.
File IO and Capturing

After that, you can simply apply any image processing filters that are needed and then show the image via

```cpp
void imshow(const string& winname,
            InputArray mat)
```

Alternatively, you can convert the image and pass it onto VTK using the code fragment on the next slides.
File IO and Capturing

```cpp
void fromMat2Vtk( cv::Mat src,
                 vtkImageData* dest ) {
    vtkImageImport *importer =
        vtkImageImport::New();
    Mat frame;
    cvtColor( src, frame, COLOR_BGR2RGB);
    if (dest) { importer->SetOutput( dest ); } }
    importer->SetDataSpacing( 1, 1, 1 );
    importer->SetDataOrigin( 0, 0, 0 );
    importer->SetWholeExtent( 0, frame.size().width-1, 0, frame.size().height-1, 0, 0 );
```
File IO and Capturing

```cpp
importer->SetDataExtentToWholeExtent();
importer->SetDataScalarTypeToUnsignedChar();
importer->SetNumberOfScalarComponents( frame.channels() );
importer->SetImportVoidPointer( frame.data );
importer->Update();
```

**Image Thresholding**

Fixed threshold;
Adaptive threshold;
Adaptive Thresholding

Fixed thresholding may not work well where image has different lighting conditions in different areas. In that case, we go for adaptive thresholding. In this, the algorithm calculates the threshold for a small region of the image. So we get different thresholds for different regions of the same image and it gives us better results for images with varying illumination:

```python
cv2.ADAPTIVE_THRESH_MEAN_C
```

threshold value is the mean of neighborhood area.

```python
cv2.ADAPTIVE_THRESH_GAUSSIAN_C
```

threshold value is the weighted sum of neighborhood values where weights are a Gaussian window.
Adaptive Thresholding

Example:
Image Thresholding Examples

Source picture  Fixed threshold  Adaptive threshold
Statistics

min, max, mean value, standard deviation over the image

Norms C, L1, L2

Multidimensional histograms

Spatial moments up to order 3 (central, normalized, Hu)

In addition to simple norm calculation, there is a function that finds the norm of the difference between two images.
Multidimensional Histograms

Histogram operations: calculation, normalization, comparison, back project

Histograms types:
- Dense histograms
- Signatures (balanced tree)

EMD (earth mover distance) algorithm:
The EMD computes the distance between two distributions (sets of weighted points), which are represented by signatures. The signatures are sets of weighted features that capture the distributions. The features can be of any type and in any number of dimensions, and are defined by the user. The EMD is defined as the minimum amount of work needed to change one signature into the other.
EMD – a method for the histograms comparison

\[ p_i \in P, \ 1 \leq i \leq |P|, \ q_j \in Q, \ 1 \leq j \leq |Q|, \text{— two histograms} \]

\[ EMD (P, Q) = \sum_{i,j} f_{ij} \cdot d(p_i, q_j) \]

\[ f_{ij} \text{— weight coefficients}, \]

\[ d(p_i, q_j) \text{— the distance between the elements } p_i \text{ and } q_j. \]
Image Pyramids

Gaussian and Laplacian pyramids
Image segmentation by pyramids
Gaussian

Use a Gaussian filter to blur image or down-sample it. A Gaussian filter simply uses the Gaussian distribution function to derive a filter matrix that describes how neighboring pixels are averaged.
Laplacian

Laplacian Pyramids are formed from the Gaussian Pyramids. There is no exclusive function for that. Laplacian pyramid images are like edge images only. Most of its elements are zeros. They are used in image compression. A level in Laplacian Pyramid is formed by the difference between that level in Gaussian Pyramid and expanded version of its upper level in Gaussian Pyramid.

Laplacian function:  

\[ \text{Laplace}(f) = \frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} \]

Filter kernel for Laplacian:

\[
\begin{bmatrix}
0 & 1 & 0 \\
1 & -4 & 1 \\
0 & 1 & 0 \\
\end{bmatrix}
\]
Image Pyramids

Gaussian and Laplacian
Pyramid-based color segmentation

On still pictures  And on movies
Morphological Operations

Two basic morphology operations using structuring element:

- erosion
- dilation

More complex morphology operations:

- opening
- closing
- morphological gradient
- top hat
- black hat
Morphological Operations

Morphological transformations are some simple operations based on the image shape. It is normally performed on binary images. It needs two inputs, one is our original image, second one is called **structuring element** or **kernel** which decides the nature of operation. Two basic morphological operators are Erosion and Dilation. Then its variant forms like Opening, Closing, Gradient etc also comes into play. We will see them one-by-one with help of following image:
Morphological Operations

Erosion

The basic idea of erosion is just like soil erosion only, it erodes away the boundaries of foreground object (Always try to keep foreground in white). So what it does? The kernel slides through the image (as in 2D convolution). A pixel in the original image (either 1 or 0) will be considered 1 only if all the pixels under the kernel is 1, otherwise it is eroded (made to zero).

![Image of erosion example]
Morphological Operations

Dilation

It is just opposite of erosion. Here, a pixel element is '1' if at least one pixel under the kernel is '1'. So it increases the white region in the image or size of foreground object increases. Normally, in cases like noise removal, erosion is followed by dilation. Because, erosion removes white noises, but it also shrinks our object. So we dilate it. Since noise is gone, they won't come back, but our object area increases. It is also useful in joining broken parts of an object.
Morphological Operations

Opening

Opening is just another name of erosion followed by dilation. It is useful in removing noise, as we explained above. Here we use the function, `cv2.morphologyEx()`
Morphological Operations

Closing

Closing is reverse of Opening, **Dilation followed by Erosion**. It is useful in closing small holes inside the foreground objects, or small black points on the object.

![Illustration of Closing operation]
Morphological Operations

Morphological Gradient

It is the difference between dilation and erosion of an image.

The result will look like the outline of the object.
Morphological Operations

Top Hat

It is the difference between input image and Opening of the image. Below example is done for a 9x9 kernel.

![Example Image]
Morphological Operations

Black Hat

It is the difference between the closing of the input image and input image.
Morphological Operations Examples

Morphology - applying Min-Max. Filters and its combinations
**Distance Transform**

Calculate the distance for all non-feature points to the closest feature point

Two-pass algorithm, 3x3 and 5x5 masks, various metrics predefined
Flood Filling

Simple Gradient

Original image  Tolerance interval ± 5  Tolerance interval ± 6
Feature Detection

Fixed filters (Sobel operator, Laplacian);
Optimal filter kernels with floating point coefficients (first, second derivatives, Laplacian)
Special feature detection (corners)
Canny operator
Hough transform (find lines and line segments)
Gradient runs
Sobel filter

Edges in an image become apparent when looking at the change between neighboring pixels. The Sobel filter is designed to detect just that. It approximates the image gradient, i.e. change of pixels, by applying a filter kernel in horizontal and vertical direction and then combining the results:

\[
G_x = \begin{bmatrix}
-1 & 0 & +1 \\
-2 & 0 & +2 \\
-1 & 0 & +1
\end{bmatrix} \ast I
\]

\[
G_y = \begin{bmatrix}
-1 & -2 & -1 \\
0 & 0 & 0 \\
+1 & +2 & +1
\end{bmatrix} \ast I
\]

\[
G = \sqrt{G_x^2 + G_y^2}
\]
Sobel filter: result
Canny Edge Detector

Multi-stage process:

Noise Reduction

Since edge detection is susceptible to noise in the image, first step is to remove the noise in the image with a 5x5 Gaussian filter.

Finding Intensity Gradient of the Image

Smoothened image is then filtered with a Sobel kernel in both horizontal and vertical direction to get first derivative in horizontal direction ($G_x$) and vertical direction ($G_y$). From these two images, we can find edge gradient and direction for each pixel as $\sqrt{G_x^2 + G_y^2}$.
Canny Edge Detector
Non-maximum Suppression

After getting gradient magnitude and direction, a full scan of image is done to remove any unwanted pixels which may not constitute the edge. For this, at every pixel, pixel is checked if it is a local maximum in its neighborhood in the direction of gradient.
Canny Edge Detector

Hysteresis Thresholding

This stage decides which are all edges are really edges and which are not. For this, we need two threshold values, minVal and maxVal. Any edges with intensity gradient more than maxVal are sure to be edges and those below minVal are sure to be non-edges, so discarded. Those who lie between these two thresholds are classified edges or non-edges based on their connectivity. If they are connected to "sure-edge" pixels, they are considered to be part of edges. Otherwise, they are also discarded.
Canny Edge Detector

Department of Computer Science and Engineering
Harris Corner Detection

This algorithm basically finds the difference in intensity for a displacement of \((u,v)\) in all directions:

\[
E(u, v) = \sum_{x,y} w(x, y) \left[ I(x + u, y + v) - I(x, y) \right]^2
\]

We have to maximize this function \(E(u,v)\) for corner detection. That means, we have to maximize the second term. Applying Taylor Expansion to above equation and using some mathematical steps, we get the final equation as:

\[
E(u, v) \approx [u \ v] \ M \begin{bmatrix} u \\ v \end{bmatrix} \\
M = \sum_{x,y} w(x, y) \begin{bmatrix} I_x I_x & I_x I_y \\ I_x I_y & I_y I_y \end{bmatrix}
\]

Here, \(I_x\) and \(I_y\) are image derivatives in \(x\) and \(y\) directions respectively, which can be computed via Sobel.
Harris Corner Detection

We can then look at the eigenvalues $\lambda_1$ and $\lambda_2$, which decide whether a region is corner, edge or flat.

- When $|R|$ is small, which happens when $\lambda_1$ and $\lambda_2$ are small, the region is flat.
- When $R < 0$, which happens when $\lambda_1 \gg \lambda_2$ or vice versa, the region is edge.
- When $R$ is large, which happens when $\lambda_1$ and $\lambda_2$ are large and $\lambda_1 \sim \lambda_2$, the region is a corner.
Harris Corner Detection

Result:
Hough Transform

Any line can be represented in two terms, \((\rho, \theta)\), where \(\rho\) is the perpendicular distance from origin to the line, and \(\theta\) is the angle formed by this perpendicular line and horizontal axis measured in counter-clockwise. So first it creates a 2D array or accumulator (to hold values of two parameters) and it is set to 0 initially. Let rows denote the \(\rho\) and columns denote the \(\theta\). Size of array depends on the accuracy you need. Suppose you want the accuracy of angles to be 1 degree, you need 180 columns. For \(\rho\), the maximum distance possible is the diagonal length of the image. So taking one pixel accuracy, number of rows can be diagonal length of the image.
Hough Transform

- Standard Hough Transform
- Probabilistic Hough Transform

Detects lines in a binary image
Background Subtraction

Background subtraction is a common and widely used technique for generating a foreground mask (namely, a binary image containing the pixels belonging to moving objects in the scene) by using static cameras.

![Diagram of background subtraction process](image.png)
Background Subtraction

The threshold parameter is important as two images taken with even the same camera will likely not be identical. Thus, a threshold parameter allows for some variance. Often times, blurring the images, e.g. with a Gaussian filter, is used to make this approach work with similar but not identical images.

OpenCV provides different approaches for such a background subtraction algorithm.
Background Subtraction

BackgroundSubtractorMOG

It is a Gaussian Mixture-based Background/Foreground Segmentation Algorithm. It was introduced in the paper "An improved adaptive background mixture model for real-time tracking with shadow detection" by P. KadewTraKuPong and R. Bowden in 2001. It uses a method to model each background pixel by a mixture of K Gaussian distributions (K = 3 to 5). The weights of the mixture represent the time proportions that those colors stay in the scene. The probable background colors are the ones which stay longer and more static.
Background Subtraction

import numpy as np
import cv2
cap = cv2.VideoCapture('vtest.avi')
fgbg = cv2.createBackgroundSubtractorMOG()
while(1):
    ret, frame = cap.read()
    fgmask = fgbg.apply(frame)
    cv2.imshow('frame', fgmask)
    k = cv2.waitKey(30) & 0xff
    if k == 27:
        break

cap.release()
cv2.destroyAllWindows()
Background Subtraction

**BackgroundSubtractorMOG2**

It is also a Gaussian Mixture-based Background/Foreground Segmentation Algorithm. It is based on two papers by Z. Zivkovic, "Improved adaptive Gaussian mixture model for background subtraction" in 2004 and "Efficient Adaptive Density Estimation per Image Pixel for the Task of Background Subtraction" in 2006. One important feature of this algorithm is that it selects the appropriate number of Gaussian distribution for each pixel. (Remember, in last case, we took a K Gaussian distributions throughout the algorithm). It provides better adaptability to varying scenes due illumination changes etc.
Background Subtraction

**BackgroundSubtractorMOG2 - Results**

```python
import numpy as np
import cv2
cap = cv2.VideoCapture('vtest.avi')
fgbg = cv2.createBackgroundSubtractorMOG2()
while(1):
    ret, frame = cap.read()
    fgmask = fgbg.apply(frame)
    cv2.imshow('frame', fgmask)
    k = cv2.waitKey(30) & 0xff
    if k == 27:
        break
cap.release()
cv2.destroyAllWindows()
```
Background Subtraction

BackgroundSubtractorGMG

This algorithm combines statistical background image estimation and per-pixel Bayesian segmentation. It was introduced by Andrew B. Godbehere, Akihiro Matsukawa, Ken Goldberg in their paper "Visual Tracking of Human Visitors under Variable-Lighting Conditions for a Responsive Audio Art Installation" in 2012. As per the paper, the system ran a successful interactive audio art installation called “Are We There Yet?” from March 31 - July 31 2011 at the Contemporary Jewish Museum in San Francisco, California.
Background Subtraction

BackgroundSubtractorGMG (continued)

It uses first few (120 by default) frames for background modelling. It employs a probabilistic foreground segmentation algorithm that identifies possible foreground objects using Bayesian inference. The estimates are adaptive; newer observations are more heavily weighted than old observations to accommodate variable illumination. Several morphological filtering operations like closing and opening are done to remove unwanted noise. You will get a black window during first few frames.
import numpy as np
import cv2
cap = cv2.VideoCapture('vtest.avi')
kernel = cv2.getStructuringElement(cv2.MORPH_ELLIPSE,(3,3))
fgbg = cv2.createBackgroundSubtractorGMG()
while(1):
    ret, frame = cap.read()
    fgmask = fgbg.apply(frame)
    fgmask = cv2.morphologyEx(fgmask, cv2.MORPH_OPEN, kernel)
cv2.imshow('frame',fgmask)
k = cv2.waitKey(30) & 0xff
if k == 27:
    break
cap.release()
cv2.destroyAllWindows()
Background Subtraction

Further clean-up of the image may be necessary. For example, a tree waving in the wind will likely leave residue in the image after background connection. This type of noise can be cleaned up by despeckle filters or the connected-components algorithm.
Contour Retrieving

The contour representation:

- Chain code (Freeman code)
- Polygonal representation

Chain code for the curve: 34445670007654443

Contour representation
Hierarchical representation of contours
Contours Examples

Source Picture
(300x600 = 180000 pts total)

Retrieved Contours
(<1800 pts total)

After Approximation
(<180 pts total)

And it is rather fast: ~70 FPS for 640x480 on complex scenes
Contour algorithms

OpenCV implements different types of contour algorithms. A polynomial contour can be retrieved like this:

epsilon = 0.1*cv2.arcLength(cnt,True)
approx = cv2.approxPolyDP(cnt,epsilon,True)

epsilon = 0.01*cv2.arcLength(cnt,True)
approx = cv2.approxPolyDP(cnt,epsilon,True)
Contour algorithms

Convex Hull:

$$\text{hull} = \text{cv2.convexHull}(\text{points}, \text{hull}, \text{clockwise}, \text{returnPoints})$$
Contour algorithms

Bounding Rectangle (straight or rotated):

\[
x, y, w, h = cv2.boundingRect(cnt)
\]
\[
cv2.rectangle(img, (x, y), (x+w, y+h), (0, 255, 0), 2)
\]
\[
rect = cv2.minAreaRect(cnt)
\]
\[
box = cv2.boxPoints(rect)
\]
\[
box = np.int0(box)
\]
\[
cv2.drawContours(img, [box], 0, (0, 0, 255), 2)
\]
Contour algorithms

Minimum Enclosing Circle:

\[(x, y), \text{radius} = \text{cv2.minEnclosingCircle}(\text{cnt})\]

\[\text{center} = (\text{int}(x), \text{int}(y))\]

\[\text{radius} = \text{int}(\text{radius})\]

\[\text{cv2.circle}(\text{img}, \text{center}, \text{radius}, (0, 255, 0), 2)\]
Contour algorithms

Fitting an Ellipse:

```python
ellipse = cv2.fitEllipse(cnt)
CV2.ellipse(img, ellipse, (0,255,0), 2)
```
Contour algorithms

Fitting a Line:

```python
rows, cols = img.shape[:2]
[vx, vy, x, y] = cv2.fitLine(cnt, cv2.DIST_L2, 0, 0.01, 0.01)
lefty = int((-x*vy/vx) + y)
righty = int(((cols-x)*vy/vx)+y)
cv2.line(img, (cols-1, righty), (0, lefty), (0, 255, 0), 2)
```

Hierarchical Representation of Contours

A contour is represented with a binary tree

Given the binary tree, the contour can be retrieved with arbitrary precision

The binary tree is quasi invariant to translations, rotations and scaling
Contours matching

Matching based on hierarchical representation of contours
Geometry

Properties of contours: (perimeter, area, convex hull, convexity defects, rectangle of minimum area)

Fitting: (2D line, 3D line, circle, ellipse)

Pair-wise geometrical histogram
Pair-wise geometrical histogram (PGH)

PGH can measure similarity between objects. It is a generalization of the chain code histogram (CCH):
Count the number of each kind of steps in the Freeman chain code representation of the contour
Pair-wise geometrical histogram (PGH)

The PGH is constructed as follows: Each of the edges of the polygon is successively chosen to be the “base edge”. Then each of the other edges is considered relative to that base edge and three values are computed: $d_{\text{min}}$, $d_{\text{max}}$, and $\theta$. $D_{\text{min}}$ is the smallest distance between the two edges, $D_{\text{max}}$ is the largest, and $\theta$ is the angle between them. The PGH is the 2D histogram whose dimensions are the angle and the distance.
Pair-wise geometrical histogram (PGH)

\[ f_{PGH} = \left[ E_r(1), E_r(2), \ldots E_r(N), E_c(1), E_c(2), \ldots E_c(M) \right]^T, \]

\[ E_r(i) = \sum_j j \cdot p(i, j) / \sum_j p(i, j), \]

\[ E_c(j) = \sum_i i \cdot p(i, j) / \sum_i p(i, j). \]

Matthew Turk and Alex Pentland

*J. Cognitive Neuroscience*

1991
Linear subspaces

Classification can be expensive:

- Big search prob (e.g., nearest neighbors) or store large PDF's

Suppose the data points are arranged as above

Idea—fit a line, classifier measures distance to line

convert $x$ into $v_1$, $v_2$ coordinates

$x \rightarrow ((x - \bar{x}) \cdot v_1, (x - \bar{x}) \cdot v_2)$

What does the $v_2$ coordinate measure?
- distance to line
- use it for classification—near 0 for orange pts

What does the $v_1$ coordinate measure?
- position along line
- use it to specify which orange point it is
Dimensionality reduction

We can represent the orange points with only their \( v_1 \) coordinates (since \( v_2 \) coordinates are all essentially 0)

This makes it much cheaper to store and compare points

A bigger deal for higher dimensional problems
Linear subspaces

Consider the variation along direction $\mathbf{v}$ among all of the orange points:

$$\text{var}(\mathbf{v}) = \sum_{\text{orange point } x} \|(x - \bar{x})^T \cdot \mathbf{v}\|^2$$

What unit vector $\mathbf{v}$ minimizes $\text{var}$?

$$\mathbf{v}_2 = \min_{\mathbf{v}} \{\text{var}(\mathbf{v})\}$$

What unit vector $\mathbf{v}$ maximizes $\text{var}$?

$$\mathbf{v}_1 = \max_{\mathbf{v}} \{\text{var}(\mathbf{v})\}$$

Solution: $\mathbf{v}_1$ is eigenvector of $\mathbf{A}$ with largest eigenvalue

$\mathbf{v}_2$ is eigenvector of $\mathbf{A}$ with smallest eigenvalue
Principal component analysis

Suppose each data point is N-dimensional

Same procedure applies:

\[ \text{var}(v) = \sum_x \| (x - \bar{x})^T \cdot v \| \]
\[ = v^T A v \quad \text{where} \quad A = \sum_x (x - \bar{x})(x - \bar{x})^T \]

The eigenvectors of \( A \) define a new coordinate system

- eigenvector with largest eigenvalue captures the most variation among training vectors \( x \)
- eigenvector with smallest eigenvalue has least variation

We can compress the data using the top few eigenvectors

- corresponds to choosing a “linear subspace”
  - represent points on a line, plane, or “hyper-plane”
- these eigenvectors are known as the principal components
The space of faces

An image is a point in a high dimensional space

An $N \times M$ image is a point in $\mathbb{R}^{NM}$

We can define vectors in this space as we did in the 2D case
Dimensionality reduction

The set of faces is a “subspace” of the set of images. We can find the best subspace using PCA. This is like fitting a “hyper-plane” to the set of faces spanned by vectors $v_1, v_2, \ldots, v_K$. Any face $x \approx \bar{x} + a_1 v_1 + a_2 v_2 + \ldots + a_k v_k$.
Eigenfaces

PCA extracts the eigenvectors of $\mathbf{A}$

- Gives a set of vectors $\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3, \ldots$
- Each vector is a direction in face space
  what do these look like?
Projecting onto the eigenfaces

The eigenfaces $v_1, \ldots, v_K$ span the space of faces.

A face is converted to eigenface coordinates by

$$x \rightarrow \left( \begin{array}{c} (x - \bar{x}) \cdot v_1 \\ a_1 \\ (x - \bar{x}) \cdot v_2 \\ a_2 \\ \vdots \\ (x - \bar{x}) \cdot v_K \\ a_K \end{array} \right)$$

$$x \approx \bar{x} + a_1 v_1 + a_2 v_2 + \ldots + a_K v_K$$
Recognition with eigenfaces

Algorithm

1. Process the image database (set of images with labels)
   - Run PCA—compute eigenfaces
   - Calculate the K coefficients for each image
2. Given a new image (to be recognized) $\mathbf{x}$, calculate K coefficients
   $$\mathbf{x} \rightarrow (a_1, a_2, \ldots, a_K)$$
3. Detect if $\mathbf{x}$ is a face
   $$\|\mathbf{x} - (\mathbf{x} + a_1 \mathbf{v}_1 + a_2 \mathbf{v}_2 + \ldots + a_K \mathbf{v}_K)\| < \text{threshold}$$
4. If it is a face, who is it?
   Find closest labeled face in database
   nearest-neighbor in $\mathbf{K}$-dimensional space
Choosing the dimension $K$

How many eigenfaces to use?

Look at the decay of the eigenvalues

the eigenvalue tells you the amount of variance “in the direction” of that eigenface

ignore eigenfaces with low variance
Eigen objects (continued)

Hidden Markov Model

Hidden Markov Models (HMMs) are a class of statistical models used to characterize the observable properties of a signal. HMMs consist of two interrelated processes:

• an underlying, unobservable Markov chain with a finite number of states governed by a state transition probability matrix and an initial state probability distribution, and

• a set of observations, defined by the observation density functions associated with each state.
**Hidden Markov Model**

**Face detection and cropping block:** this is the first stage of any face recognition system and the key difference between a semi-automatic and a fully automatic face recognizer. In order to make the recognition system fully automatic, the detection and extraction of faces from an image should also be automatic. Face detection also represents a very important step before face recognition, because the accuracy of the recognition process is a direct function of the accuracy of the detection process.
Hidden Markov Model

**Pre-processing block**: the face image can be treated with a series of pre-processing techniques to minimize the effect of factors that can adversely influence the face recognition algorithm. The most critical of these are *facial pose* and *illumination*.
Hidden Markov Model

**Feature extraction block**: in this step the features used in the recognition phase are computed. These features vary depending on the automatic face recognition system used. For example, the first and most simplistic features used in face recognition were the geometrical relations and distances between important points in a face, and the recognition 'algorithm' matched these distances.
Hidden Markov Model

**Face recognition block**: this consists of 2 separate stages: a *training process*, where the algorithm is fed samples of the subjects to be learned and a distinct model for each subject is determined; and an *evaluation process* where a model of a newly acquired test subject is compared against all existing models in the database and the most closely corresponding model is determined. If these are sufficiently close a recognition event is triggered.
Hidden Markov Model

Based on the extracted features of a face (eyes, nose, mouth, …), the HMM can then be trained to recognize specific faces. For this, an enhanced version of the so-called Viterbi algorithm known as *double embedded Viterbi* was developed. It involves applying the Viterbi algorithm to both the embedded HMMs and to the global, or top-level HMM, hence the name.
Embedded HMM for Face Recognition

- Face ROI partition
Face recognition using Hidden Markov Models

- One person – one HMM
- Stage 1 – Train every HMM

Stage 2 – Recognition

\[ P_i \text{ - probability} \]

Choose \[ \text{max}(P_i) \]
OpenCV Functionality

- Structural Analysis
- Object Recognition
- Motion Analysis and Object Tracking
- 3D Reconstruction
Motion Analysis and Object Tracking

Motion templates
Optical flow
Active contours
Estimators
Motion Segmentation Algorithm

Two-pass algorithm labeling all motion segments

Clapping boxes together and down
Motion Templates Example

• Motion templates allow to retrieve the dynamic characteristics of the moving object
Optical Flow

Block matching technique
Horn & Schunck technique
Lucas & Kanade technique
Pyramidal LK algorithm
6DOF (6 degree of freedom) algorithm

Optical flow equations:

\[
I(x + dx, y + dy, t + dt) = I(x, y, t);
\]

\[- \frac{\partial I}{\partial t} = \frac{\partial I}{\partial x} \cdot \frac{dx}{dt} + \frac{\partial I}{\partial y} \cdot \frac{dy}{dt};\]

\[
G \cdot \partial X = b,
\]

\[
\partial X = (\partial x, \partial y),
G = \sum \begin{bmatrix} I_x^2 & I_x I_y \\ I_x I_y & I_y^2 \end{bmatrix},
\]

\[
b = \sum I_t \begin{bmatrix} I_x \\ I_y \end{bmatrix}.
\]
Pyramidal Implementation of the optical flow algorithm

Image Pyramid Representation

J image       I image

Iterative Lucas – Kanade Scheme

Location of point $u$ on image $u^L = u/2^L$

Spatial gradient matrix $g = \sum \begin{bmatrix} I_x^2, I_x I_y \\ I_x I_y, I_y^2 \end{bmatrix}$

Standard Lucas – Kanade scheme for optical flow computation at level $L$ $d^L$

Guess for next pyramid level $L - 1$

Finally,

$g^{L+1} = 2(g^L + d^L)$

$d = d^0 + g^0$

$V = U + d$
6DOF Algorithm

Parametrical optical flow equations:

\[ \mathbf{X} = \pi (s). \]

\[ \nabla I = \frac{\partial I}{\partial s} = \frac{\partial I}{\partial \mathbf{X}} \cdot \frac{\partial \pi}{\partial s} \]

\[
\sum_{i=1}^{N} \sum_{ROI} \nabla I_i^T \cdot \nabla I_i \cdot ds = \sum_{i=1}^{N} \sum_{ROI} I_{t_i} \cdot \nabla I_i^T
\]
Active Contours

Snake energy:
Internal energy:
External energy:
Two external energy types:

\[ E = E_{\text{int}} + E_{\text{ext}} \]
\[ E_{\text{int}} = E_{\text{cont}} + E_{\text{curv}} \]
\[ E_{\text{ext}} = E_{\text{img}} + E_{\text{con}} \]

\[ E_{\text{img}} = -I, \]
\[ E_{\text{img}} = -\| \text{grad} \ (I) \|, \]
\[ E = \alpha \cdot E_{\text{cont}} + \beta \cdot E_{\text{curv}} + \gamma \cdot E_{\text{img}} \Rightarrow \min \]
Estimators

Kalman filter
ConDensation filter
Kalman object tracker

The idea of using a Kalman filter for object tracking is to attenuate the noise associated with the position detection of the object based on estimating the system state. It can also be used to predict the position based on the state transition model when no new measurements are available.

Camera Calibration

View Morphing

POSIT
Camera Calibration

Define intrinsic and extrinsic camera parameters. Define Distortion parameters

\[ p = A [RT ] P , \]
\[ A = \begin{bmatrix} f_x & 0 & c_x \\ 0 & f_y & c_y \\ 0 & 0 & 1 \end{bmatrix} , \quad R = \begin{bmatrix} r_{11} & r_{12} & r_{13} \\ r_{21} & r_{22} & r_{23} \\ r_{31} & r_{32} & r_{33} \end{bmatrix} , \quad T = \begin{bmatrix} t_1 \\ t_2 \\ t_3 \end{bmatrix} , \quad P = [X,Y,Z] , \quad p = [u,v] \]

\[ \tilde{u} = u + (u - c_x) \cdot [k_1 \cdot r^2 + k_2 \cdot r^4 + 2 p_1 y + p_2 (r^2 / x + 2x)] , \]
\[ \tilde{v} = v + (v - c_y) \cdot [k_1 \cdot r^2 + k_2 \cdot r^4 + 2 p_2 x + p_1 (r^2 / y + 2y)] , \]
\[ r^2 = x^2 + y^2 . \]
Camera Calibration

Now, camera calibration can be done by holding a checkerboard in front of the camera for a few seconds. After that, you'll get:

- 3D view of etalon
- Un-distorted image

Win32 platforms:

Win9x/WinNT/Win2000

**C++ Compiler** (makefiles for Visual C++ 6.0, Intel C++ Compiler 5.x, Borland C++ 5.5, Mingw GNU C/C++ 2.95.3 are included) for core libraries

Visual C++ to build the most of demos

DirectX 8.x SDK for directshow filters

ActiveTCL 8.3.3 for TCL demos

IPL 2.2+ for the core library tests

Linux/*NIX:

C++ Compiler (tested with GNU C/C++ 2.95.x, 2.96, 3.0.x)

TCL 8.3.3 + BWidgets for TCL demos

Video4Linux + Camera drivers for most of demos

IPL 2.2+ for the core library tests
OpenCV structure

OpenCV

DShow filters, Demo apps, Scripting Environment

OpenCV(C++ classes, High-level C functions)

Switcher

Low level C-functions

IPP

Intel Image Processing Library

Department of Computer Science and Engineering
Data Types

Image (IplImage);
Matrix (CvMat);
Histogram (CvHistogram);

Dynamic structures (CvSeq, CvSet, CvGraph);
Spatial moments (CvMoments);
Helper data types (CvPoint, CvSize, CvTermCriteria, IplConvKernel and others).
Error Handling

There are no return error codes.

There is a global error status that can be set or checked via special functions.

By default a message box appears if error happens.
Portable GUI library (HighGUI)

Reading/Writing images in several formats (BMP, JPEG, TIFF, PXM, Sun Raster)

Creating windows and displaying images in it. HighGUI windows remember their content (no need to implement repainting callbacks)

Simple interaction facilities: trackbars, getting input from keyboard and mouse (new in Win32 version).
Portable Video Capture Library (CvCAM)

Single interface for video capture and playback under Linux and Win32
Provides callback for subsequent processing of frames from camera or AVI-file
Easy stereo from 2 USB cameras or stereo-camera
Scripting I: Hawk

Visual Environment
ANSI C interpreter (EiC) as a core
Plugin support
Interface to OpenCV, IPL and HighGUI via plugins
Video support
Scripting II: OpenCV + MATLAB

Design principles and data types organization

Working with images

Working with dynamic structures

Example
Simplicity: Use of native MATLAB types (matrices, structures), rather than introducing classes

Compatibility: … with Image Processing Toolbox

Irredundancy: matrix and basic image processing operations are not wrapped

\[ \text{[dst ...]} = \text{cv<func>}(\text{src ...}) \]

// data type conv., error handling

void mexFunction (...) { ... }

cvFunc(\text{src ...}, \text{dst ...}) \{\ldots\}
Working with Images

% erosion with 3x3 rectangular element

% strong corners detection (quality level = 0.1, min distance = 10)

% Optical Flow on pyramids: window 10*2+1x10*2+1, 4 scales

% Color object tracking, default termination criteria (epsilon = 1):
% get all the connected components of binary image,
% don’t approximate them

% get bounding box of the first contour
  % get the first child of the second contour
  % get Nx2 array of vertices of the child
  % draw the child contour

% on the image with green
% approximate all contours using Douglas-Peucker method with accuracy = 2.

% compare contours via pair-wise histogram comparison
Example:

% Camshift tracker, enhanced with noise filter

function new_window = track_obj( img, obj_hist, window, thresh )
    probimg = cvcalcbackproject( img, obj_hist );
    probimg = cvclose( probimg, 3, 2 ); % remove small holes via morphological ‘close’ operation
    probimg = cvthresh( probimg, thresh );
    contours = cvfindcontours( probimg, ‘external’ );
    mask_img = zeros(size(contours));
    for i = 1:length(contours)
        if  contous(i).rect(3)*contous(i).rect(4) < 30
            contours(i).pt = [] ; % remove small contours;
        end
    end
    mask_img = cvfillcontours( mask_img, contours, ‘w’ );
    new_window = cvcamshift( mask_img, window );
